

I still feel kinda shaky on my coding ability but I believe that I can execute this idea well and with my understanding. So, I am making a volume slider that “goes down” to turn up. I want the path for the volume slider to be super wonky and as you drag it will have popups that interrupt you trying to turn up the volume. The popups are where my data structure will come into play. I will use a Linked List for the questions and a Finite State Machine for the states that I am in (dragging, answering questions, resetting ect.). The catch is that you have to answer YES to proceed and the questions will be stupid ones that you do not *want* to answer “Yes” to. If you answer “NO” it will revert you back to the top of the volume slider. I have a photo of what I am thinking below. I think the most difficult part will be connecting the volume slider with the crazy path. I want it to be a smooth slider but if that is too difficult I will make it pointier. I was also debating making the colors change as you slide down and up. It will be backwards so your eyes will have trouble deciphering if you are going up or down.
